Dataset. Anonymisation

December 14, 2022

1 Anonymisation of 'customer_information.csv' dataset for use by Imperial researchers and government (and calculation of Kanonymity)

Anonymisation is the practice of removing identifying information from data in order to protect individuals' privacy. By anonymising data, we can ensure that sensitive information is kept secure. In this project, we aim to create an anonymised dataset by removing personally identifiable information from the original dataset whilst attempting to retain its utility and insights by using a combination of techniques such as pseudonymous identification and data perturbation.

1.1 Helper functions

The following helper functions are needed:

```
[2]: # Helper functions
     # The following variable countries were hard-coded to fix unmatched territory,
     northern_countries = ["Svalbard & Jan Mayen Islands"]
     southern_countries = ["Micronesia"]
     # Parse country into shortform
     def parse_country(country_name):
         return coco.convert(country_name, to='name_short', include_obsolete=True)
     # Convert country of birth into Hemisphere (Northern or Southern) based on
      \hookrightarrow latitude coordinates
     def country_to_hemisphere(country_name):
         try:
             if country_name in southern_countries:
                 return "Southern Hemisphere"
             elif country_name in northern_countries:
                 return "Northern Hemisphere"
             else:
                 return ("Southern" if Nominatim(user_agent="CDM").
      Geocode(parse_country(country_name)).latitude < 0 else "Northern") + "∪
      ⊶Hemisphere"
```

```
except Exception as e:
        print(e)
        return "Error"
# SHA hash function using a key and salt
def hash(to_hash, key):
    salt = os.urandom(16)
    h = hashlib.sha256()
    h.update(key)
    h.update(salt)
    h.update(to hash.encode())
    return to_hash, h.hexdigest(), salt.hex()
# To encrypt and save as encrypted file; specify file to encrypt, encrypted_
 ⇔file destination, and destination key location
def encrypt(to_encrypt, file_destination, key_location):
    key = Fernet.generate_key() # AES in CBC mode with a 128-bit key for
 \hookrightarrow encryption
    fernet = Fernet(key)
    with open(key_location, 'wb') as f:
        f.write(key)
    with open(to_encrypt, 'rb') as f:
        plaintext = f.read()
    encrypted = fernet.encrypt(plaintext)
    with open(file_destination, 'wb') as e:
        e.write(encrypted)
```

1.2 Loading required data and creating the anonymised dataframe

The original dataset is loaded, an empty output Dataframe is initialised, and a postcode reference table is loaded

```
[3]: # Read in data to be anonymised original_data = pd.read_csv("Data/customer_information.csv")

# Reading in postcode_region.csv to map given postcode to countries in the UK -___ 
'England' and 'Other'(includes Wales, Scotland, Northern Ireland)

postcode_dictionary = pd.read_csv('Data/postcode_region.csv')

# Create anon_data variable as initial data with unneeded direct identifiers__ 
-dropped

anon_data = pd.DataFrame()

postcode_dictionary.head()
```

```
[3]: Postcode Region
0 AB Other
1 AL England
2 B England
3 BA England
4 BB England
```

1.3 Adding variables to the anonymised dataset

Assigning gender and case-control status as given

```
[4]: # Assign gender
anon_data['Gender'] = original_data['gender']

# Assign case-control status
anon_data['CC.Status'] = original_data['cc_status']
anon_data.head()
```

```
[4]: Gender CC.Status
0 F 0
1 M 0
2 F 0
3 F 0
4 F 0
```

2 Anonymisation

2.1 Pseudonymisation with hashed Sample ID

Next, a unique Sample ID is created from the National Insurance Number to link the anonymised data with the reference data containing sensitive information.

```
[5]: # Clean NIN formatting and assign Sample ID as a hashed form of the NIN

key = os.urandom(16)

original_data["national_insurance_number"], anon_data['Sample.ID'], salts = □

⇒zip(*original_data["national_insurance_number"].apply(

lambda x: hash(re.sub(r'(.{2})(?!$)','\\1', x.replace(' ', '')), key)))

anon_data.head()
```

```
[5]:

3 Calculating K-anonymity using quasi-identifiers

The following code groups the quasi-identifiers specified, calculates the k-value, and returns a count of the "unique" rows.

The anonymised dataset is 2-anonymous; there are 0 unique quasi-identifier permutations.

Least-frequent quasi-identifier permutations, in ascending order:

```

4.1 Creating CSV files for the anonymised data and the reference table

29.0

0

348.0

```
[48]: # Output the files into .csv format
output_name = "anon_dataset"
anon_data.to_csv(output_name + ".csv", sep=",", index=None)
```

```
reference_table.to_csv("reference_table.csv", sep=",", index=None)
```

4.2 Encrypting the dataset

```
[49]: # Encrypt csv and delete original file encrypt(output_name + ".csv", output_name + "_encrypted.csv", "key.key") os.remove(output_name + ".csv")
```

```
[50]: pip freeze > requirements.txt
```

Note: you may need to restart the kernel to use updated packages.
